## Metal hydrides for hydrogen storage

- $\text{M} = \text{Ti, Fe, Mn, Ni, Cr}$  etc. that can react with  $\text{H}_2$  in a reversible reaction.
- The forward reaction is slightly exothermic. To release hydrogen, a small amount of heat must be supplied.
- $\text{H}_2$  is stored at a modest pressure and release at ambient pressure.

Physical & thermodynamic properties

**U**

Uranium

[Rn] 5f<sup>3</sup>6d<sup>1</sup>7s<sup>2</sup>

Actinides

## ➤ Disadvantages:

- Heavy, not suitable for portable storage.
- Hard to handle the uranium hydride. (due to its radioactivity and high pyrophoricity with oxygen)

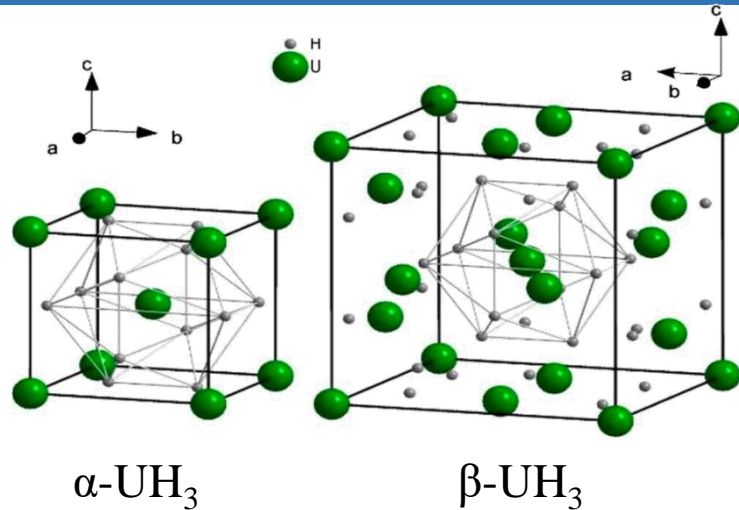

## ➤ Advantages:

- Low equilibrium pressure (< 0.1 Pa) at room temperature for less tritium loss;
- Low release temperature (400~450 °C) that can reduce the permeation loss of tritium through containment;
- Fast gas uptake/release rate that is desired for emergency use;

## Properties of Uranium hydride

# 1. Background

**Table 1**

The different phases and structural properties of uranium and uranium hydride. U [18,19], UH<sub>3</sub>, UD<sub>3</sub> [20–22] and UT<sub>3</sub> [23].

Metal/ compound	Symmetry	Lattice cell parameter (Å)	Density (g/cm <sup>3</sup> )
$\alpha$ -UH <sub>3</sub>	Cubic	4.160 ± 0.001	11.12
$\alpha$ -UD <sub>3</sub>	Cubic	4.150	11.33
$\alpha$ -UT <sub>3</sub>	Cubic	4.142 ± 0.002	11.55
$\beta$ -UH <sub>3</sub>	Cubic	6.645	10.92
$\beta$ -UD <sub>3</sub>	Cubic	6.620 ± 0.002	11.11
$\beta$ -UT <sub>3</sub>	Cubic	6.625 ± 0.003	11.29

A. Banos *et al.*, Corrosion science (2018)

## ➤ Difficulties in investigation:

- Complex behaviors of 5f electronic states;
- Limited experimental data on physical properties of uranium compounds, such as, phase diagram, magnetic properties and phonon dispersions.

S. P. Marsh, *Lasl Shock Hugoniot Data* (1980)

- Experiment shock compression data of UH<sub>3</sub> are available for pressure up to 35 GPa.

## 2. Method

- **Computational method:**

- First-principles molecular dynamics (FPMD)

- The Rankine-Hugoniot equation:

$$(E_1 - E_0) + 1/2 (V_1 - V_0)(P_0 + P_1) = 0$$

$$V_1 = V_0(1 - u_p/u_s)$$

$$P_1 - P_0 = \rho_0 u_s u_p$$

**Hugoniot**

- Electronic structures: PCF, DOS, ELF
- Physical properties: Electrical conductivity ( $\sigma$ ), thermal conductivity ( $\kappa$ ), and optical reflectivity

2×2×2 cubic supercell

- **FPMD details**

- NVT ensemble; pressure range up to 200 GPa;
- Starting at  $\rho_0=11.12 \text{ g/cm}^3$  ( $\alpha\text{-UH}_3$ ) and  $\rho_0=11.33 \text{ g/cm}^3$  for  $\alpha\text{-UD}_3$  at 300 K;
- Time steps of 0.8 fs; 8000 steps totally
- The final 4000 steps equilibrated for property calculations
- GGA and GGA+ $U$  with  $U_{\text{eff}} = 2$  and 4 eV ( $U_{\text{eff}} = U - J$ )

# 3. Results

## Hugoniots

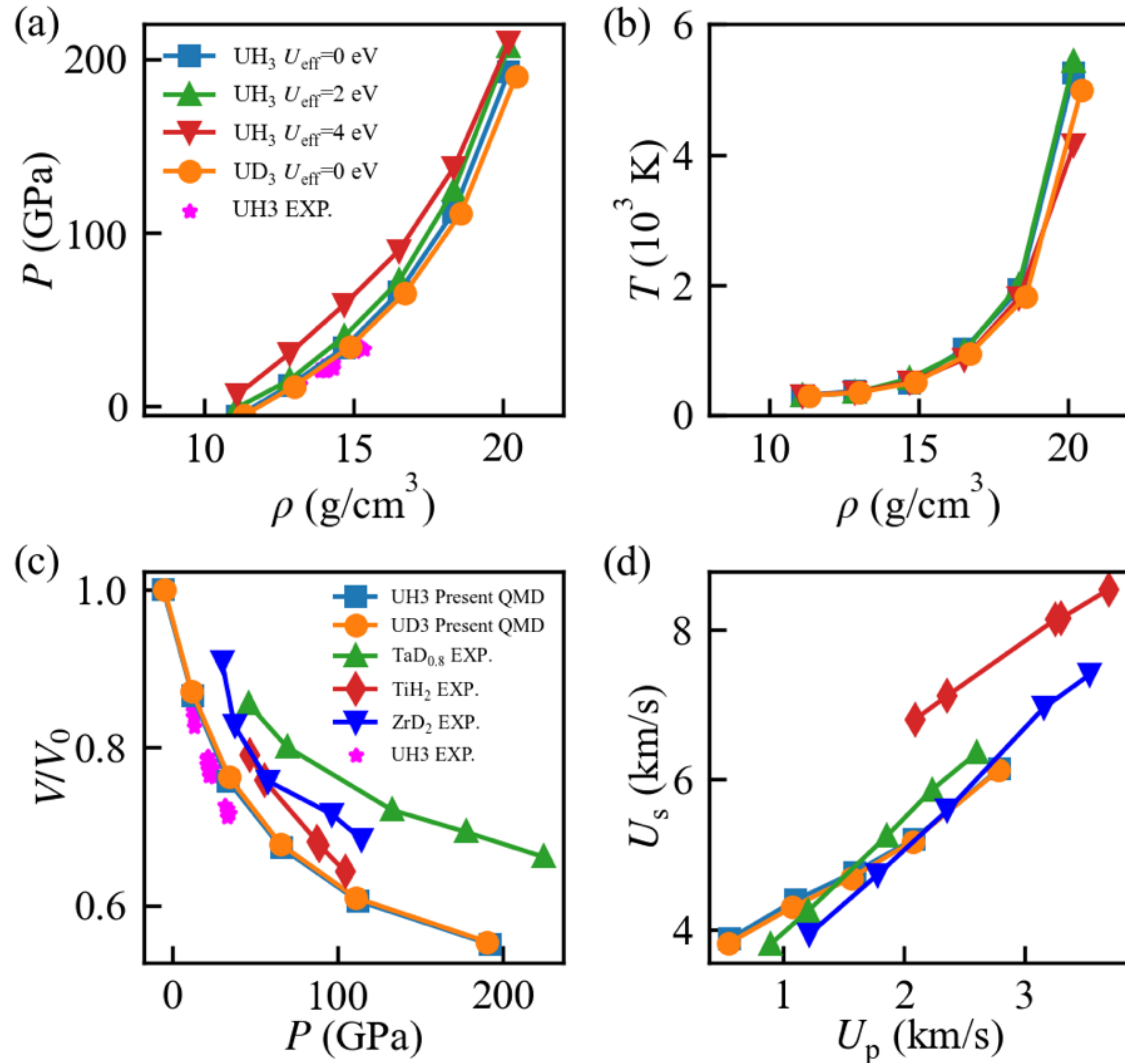

FIG. (a-b) Principal Hugoniot of UH<sub>3</sub> and UD<sub>3</sub> calculated with DFT+ $U$  method where  $U_{\text{eff}}=0, 2,$  and  $4$  eV, respectively. (c) Normalized molar volumes of hydrides and deuterides as a function of pressure along the Hugoniot curve. (d) The velocity of the shock wave front versus the particle velocity.

- UH<sub>3</sub> and UD<sub>3</sub> have a similar equation of state along the Hugoniot;
- The pressure is higher with a larger  $U_{\text{eff}}$  for the same density;
- Standard PBE calculations are more reasonable in this study according to the experimental Hugoniot.
- The behavior of UH<sub>3</sub> (UD<sub>3</sub>) under shock compression is similar to that of TiH<sub>2</sub>, which might be associated with their similar cubic structures.

# 3. Results

## Atomic structure

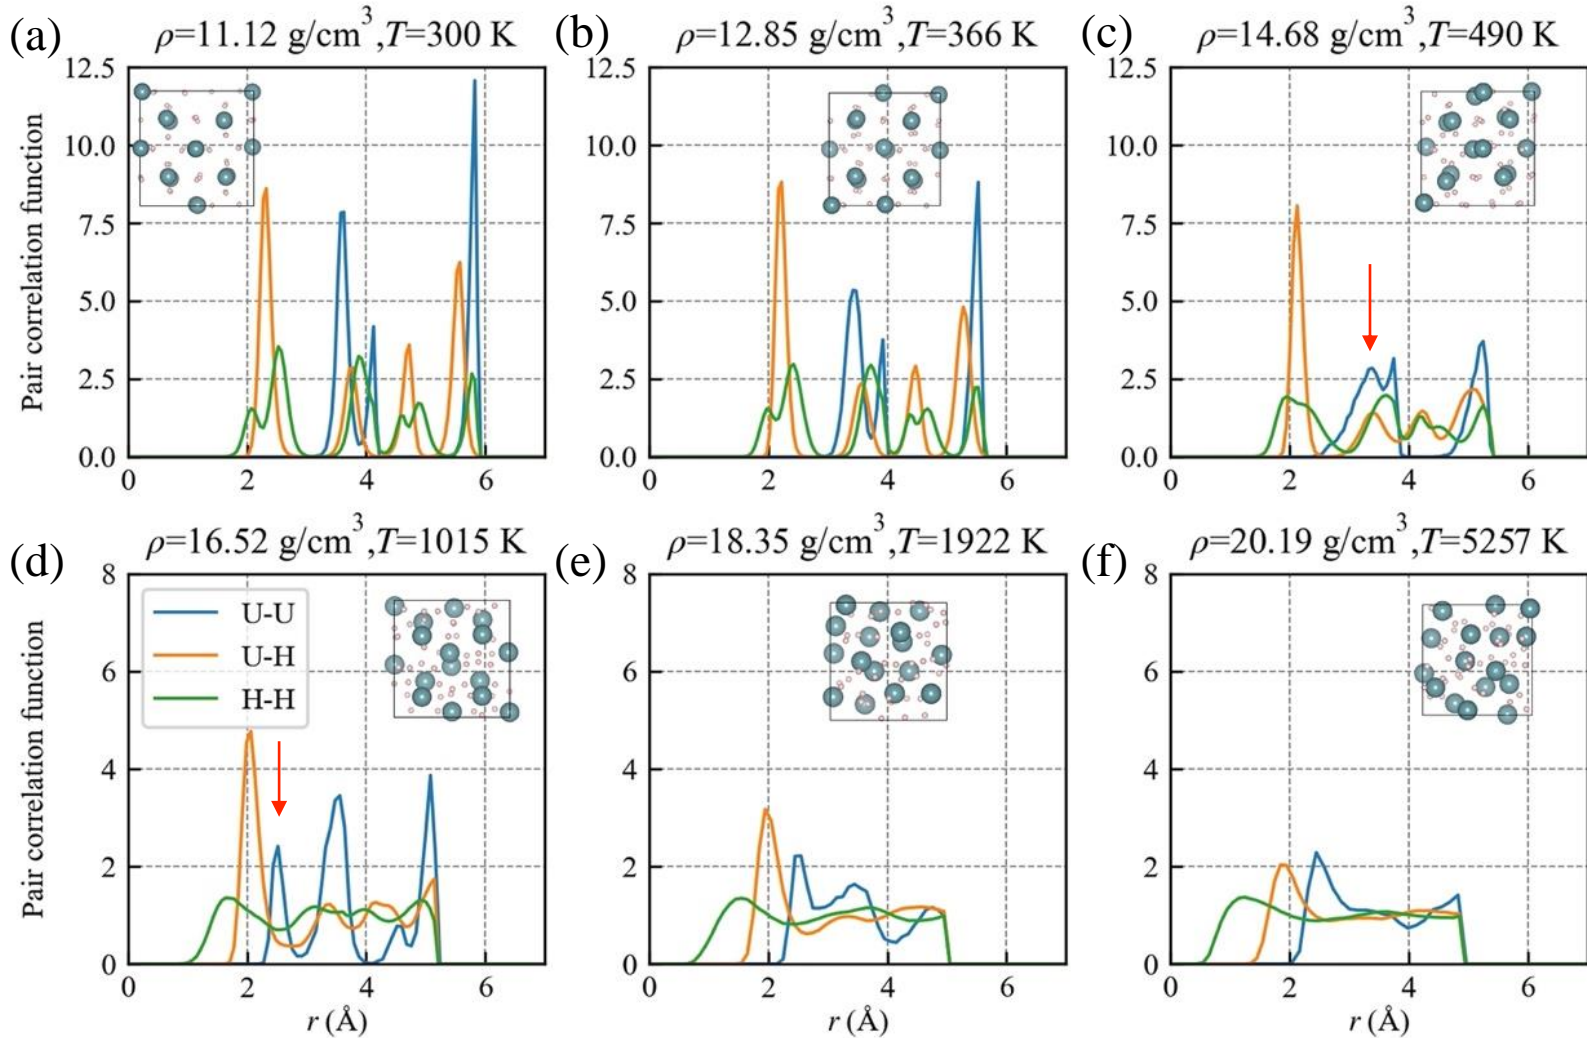

FIG. Pair-correlation functions for U-U (blue line), U-H (orange line), and H-H (green line) along the principal  $\text{UH}_3$  Hugoniot.

- (a)→(b): Peaks are clearly split and most peak values decrease slightly;
- (b)→(d): Peaks are lowered and broadened. In (d), peaks of H-H vanish. The first peak of U-H at about  $r = 2.1 \text{ \AA}$  is obviously higher than other U-H peaks; The first U-U peak at  $3.36 \text{ \AA}$  for  $\rho = 14.68 \text{ g/cm}^3$  moves to  $2.5 \text{ \AA}$  suddenly.
- (d)→(f): Peaks of U-U vanish gradually; No peak at the equilibrium distance of the hydrogen molecule at  $0.75 \text{ \AA}$ .

# 3. Results

## Density of states & Fermi weight

- (a)→(b): The electrons are relatively localized in the energy range of -10 ~ 15 eV ;
- (b)→(e): The DOS peak near the Fermi level is broadened, DOS gaps disappear due to the disordered structure after dissociation, which causes the energy levels to be continuous.
- (e)→(f): The shape of DOS is almost unchanged but slightly smoothed and the Fermi weight change obviously due to the increase in temperature.

FIG. Electron density of states of  $\alpha$ -UH<sub>3</sub> along the principal Hugoniot (blue solid line). The red dashed line shows the Fermi-weights  $f(\varepsilon - \mu)$  for corresponding temperatures.

### 3. Results

#### Electron localization function (ELF)

- U and H atoms are bonded ionically;
- H atoms deviate from the equilibrium position and show liquid-like feature in Fig. 6(d), while U atoms deviate from the equilibrium position in Fig. 6(e) at a higher density and temperature.

FIG. The electron localization functions (ELF) of (1 0 0) plane of  $\alpha\text{-UH}_3$  along the principal Hugoniot. The uranium and hydrogen atoms are denoted by blue and white balls, respectively.

# 3. Results

## Dynamic electrical conductivity

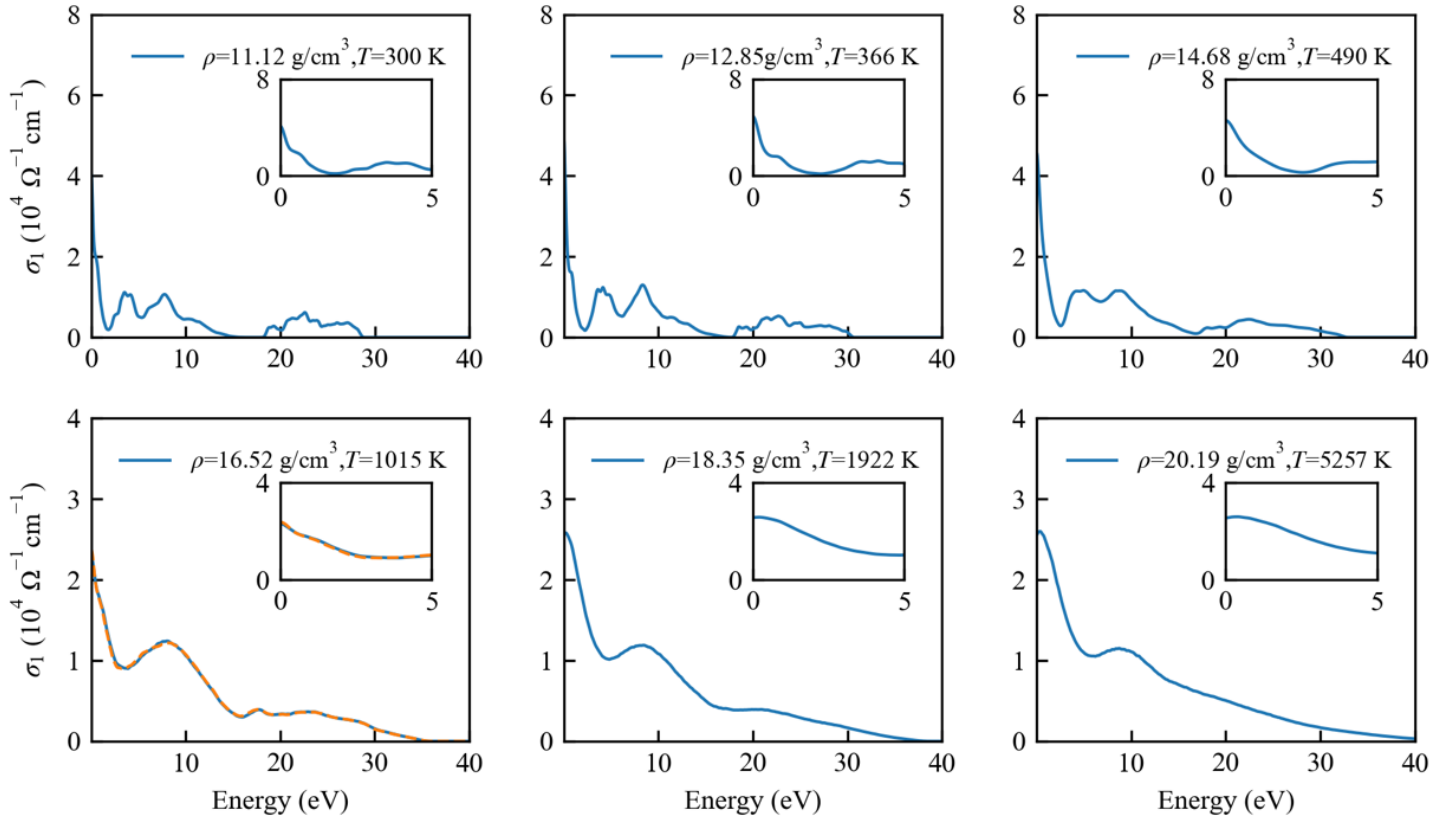

FIG. The real part of the dynamic electrical conductivity along the principal Hugoniot.

- The Kubo-Greenwood formula :

- $$\sigma_1(\omega) = \frac{2\pi}{3\omega\Omega} \sum_{\mathbf{k}} W(\mathbf{k}) \sum_{j=1}^N \sum_{i=1}^N \sum_{\alpha=1}^3 [f(\epsilon_{i,\mathbf{k}}) - f(\epsilon_{j,\mathbf{k}})] \times |\langle \Psi_{j,\mathbf{k}} | \nabla_{\alpha} | \Psi_{i,\mathbf{k}} \rangle|^2 \delta(\epsilon_{j,\mathbf{k}} - \epsilon_{i,\mathbf{k}} - \hbar\omega)$$

- $$\sigma_{dc} = L_{11} = \lim_{\omega \rightarrow 0} L_{11}(\omega)$$

- $$\kappa_e = L_{22} - \frac{L_{12}L_{21}}{L_{11}}$$

➤ Drude-like shape in the low-frequency regime with the maximum located at zero frequency that is classical for liquid metals ;

➤ The curve of  $\sigma_1(\omega)$  becomes smoother due to the distortion of the atomic structure and the temperature-induced broadening of the Fermi-Dirac distribution function, which lead to continuous density of states

# 3. Results

## Transport properties

FIG. (a) The dc conductivity along the principal Hugoniot. (b) The electrical thermal conductivity along the principal Hugoniot.

- According to  $\sigma_{dc}$ , the status of  $\alpha$ -UH<sub>3</sub> could be divided into three period:
  - 1)  $P < 12$  GPa;
  - 2)  $12 \text{ GPa} \sim 66 \text{ GPa}$ ;
  - 3)  $P > 66 \text{ GPa}$ .
- $\kappa_e$  shows a similar trend with  $\sigma_{dc}$  for the pressures below 66 GPa ;
- For  $P > 66 \text{ GPa}$ ,  $\kappa_e$  obeys the Wiedermann-Franz law,  $L = \frac{\kappa_e}{\sigma T} = \text{Constant}$ , the dramatic increase should be owing to the huge temperature increase from 1015 K to 5257 K.

# 3. Results

## Reflectivity

FIG. (a) Reflectivity as a function of photon energy for different UH<sub>3</sub> densities along the principal Hugoniot. (b) Optical reflectivity of shocked UH<sub>3</sub> for wavelengths 404 (purple square), 808 (orange circle), and 1064 nm (red triangle) along the Hugoniot.

- Kramers-Kronig relation :

$$\sigma_2(\omega) = -\frac{2}{\pi} P \int_0^{\infty} \frac{\sigma_1(\nu)\omega}{\nu^2 - \omega^2} d\nu ; \varepsilon(\omega) = \varepsilon_1(\omega) + i\varepsilon_2(\omega)$$

$$\varepsilon_1(\omega) = 1 - \frac{\sigma_2(\omega)}{\omega\varepsilon_0} ; \varepsilon_2(\omega) = \frac{\sigma_1(\omega)}{\omega\varepsilon_0} ;$$

optical refraction:  $n(\omega) + ik(\omega)$

$$n(\omega) = \frac{1}{\sqrt{2}} \sqrt{|\varepsilon(\omega)| + \varepsilon_1(\omega)} ; k(\omega) =$$

$$\frac{1}{\sqrt{2}} \sqrt{|\varepsilon(\omega)| - \varepsilon_1(\omega)}$$

$$r(\omega) = \frac{[1-n(\omega)]^2 + k(\omega)^2}{[1+n(\omega)]^2 + k(\omega)^2}$$

- The reflectivities corresponding to different wavelengths become closer under compression.

## 4. Conclusions

---

- The variation of structures and properties under shock compression can be generally divided into three periods: the density increase of solid crystal that dominated by pressure increase (<12GPa), bond dissociation process caused by both pressure and temperature increase (12~66 GPa), and the activity increase of dense fluid atoms dominated by temperature increase (66~193GPa).
- The structure of U atoms is not dissociated below 66 GPa according to the PCF. No hydrogen molecule forms which implies that U is excellent in stable storage of hydrogen under shock compression up to 66 GPa.
- Experimentally measurable dc conductivity, electrical thermal conductivity, and optical reflectivity are all associated with the structural change, providing several ways to probe the dynamic compression process.

---

Thank you very much!

Q & A
