# Formation stability of oxygen defects

Formation energies

- $O_i$  is more easily formed than  $O_v$  in  $UO_2$ , while the possibility of forming  $O_v$  and  $O_i$  is similar in  $PuO_2$
- $O_v$  is most likely to form in the second O atomic layer for both  $UO_2$  and  $PuO_2$
- The formation energy of  $O_v$  gradually tends to be flat. The formation energy of  $O_i$  changes slightly with the surface depth.

# Electronic properties

ideal

$O_v$

$O_i$

$UO_2$

$PuO_2$

PDOS

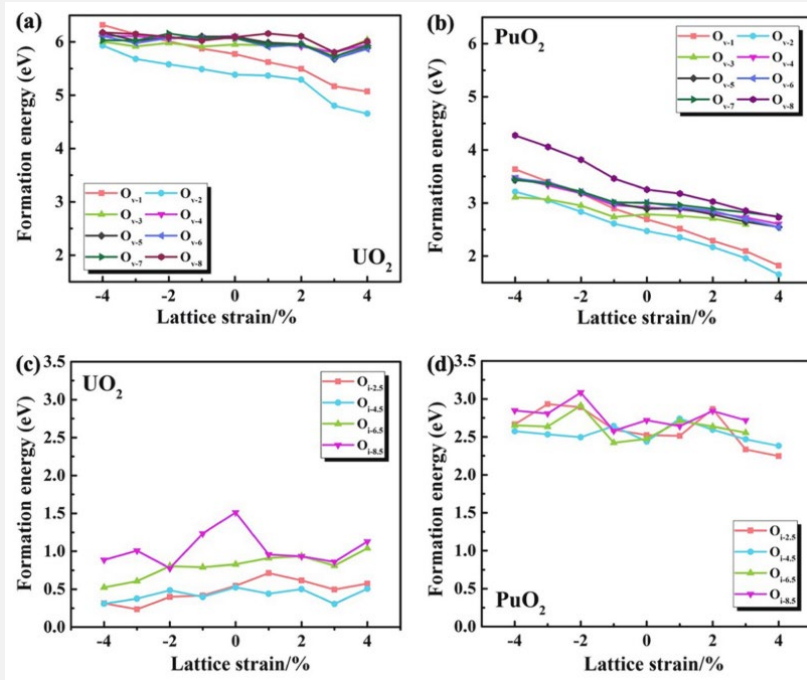

$UO_2$

$PuO_2$

CD

- ✓  $O_v$  defect states appear in the band gap of both  $UO_2$  and  $PuO_2$ .
- ✓ Compared to plutonium, uranium in  $UO_2$  is more prone to bond with additional oxygen atoms

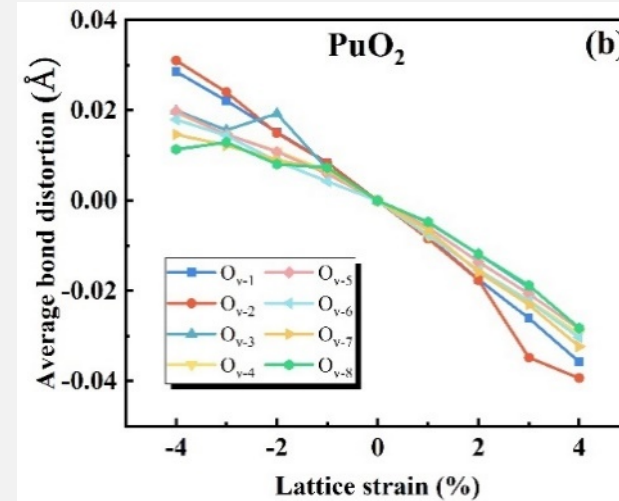

# Strain effect

- Stretching strain promote the formation of  $O_v$ , while compressive strain inhibit  $O_v$
- Lattice strain has no regular influence on the formation energy of  $O_i$

Variations of formation energy with lattice strain

# Strain effect

## Bond distortion

- Stretching and compressive strain promote the U(Pu)-O bond distortions for O<sub>v</sub> in UO<sub>2</sub> (111) and PuO<sub>2</sub> (111)
- The variation of the bond distortion induced by lattice strain of O<sub>v</sub> in UO<sub>2</sub> (111) changes gently compared with the surface layers

# Thermodynamic phase diagram

## Variation with temperature

## Variation with pressure

- The formation energy of  $\text{O}_v$  decreases with temperature, while the formation energy of  $\text{O}_i$  increase with temperature.
- The formation energies of  $\text{O}_v$  increase with the pressure, while the formation energies of  $\text{O}_i$  decrease with increasing pressure
- Stretching strain reduces the formation energy of vacancy, while compressive strain increases it, and formation of  $\text{O}_i$  is less affected by strain.
- $\text{O}_i$  is easier to form in in  $\text{UO}_2$  in the considering temperature and pressure range

# Thermodynamic phase diagram

## Phase diagram of formation of oxygen defects with different lattice strain

- Low oxygen partial pressure encourages the formation of vacancy, while high oxygen partial pressure facilitates the formation of interstitials
- Stretching strain enlarges the vacancy region and contracts the stable structure phase region, while compressive strain contracts the vacancy phase region and enlarges the stable structure region.

# 04 Conclusions

---

# Conclusions

## Structural stability

The formation of  $O_i$  is much easier than  $O_v$  in  $UO_2$ , while the formations of  $O_i$  and  $O_v$  have similar chances in  $PuO_2$ .  $O_v$  prefer to form on the sub-surface layer for both  $UO_2$  and  $PuO_2$ . Comparatively, the formation of  $O_i$  is insensitive to the incorporation depth.

## Strain response

Stretching strain reduces the formation energy of vacancy, while compressive strain increases it. Lattice strain has little effect on interstitial oxygen. This strain effect is mainly contributed by the local structural distortion, rather than the electronic hybridization.

## Electronic characters

An  $O_v$  introduces a defect state in the band gap of  $UO_2$  and  $PuO_2$ . For  $O_i$ , its electronic states hybridize with neighboring uranium atoms and results in negligible changes in the band structure of  $UO_2$ . Comparatively an  $O_i$  introduces a deep-level defect state in the band gap of  $PuO_2$ .

## Thermodynamic phase diagram

The strain-modulated formation energy phase diagrams of the oxygen defects have been established over a wide range of temperature and pressure, providing the potential strategy for controlling the type and concentration of intrinsic oxygen defects in  $UO_2$  and  $PuO_2$ .
